

# Physics 226: Particle Physics Phenomenology

## Lecture 1: Introduction

Fall 2016  
August 25 , 2015

# Physics 226: Particle Physics Phenomenology

- Primary theme of this class:
  - ▶ Interplay between theory and experiment
    - Surprising experimental results lead to theoretical breakthroughs
    - Brilliant theoretical ideas both guide experiment and allow us to interpret measurements
- Understanding of particle physics expressed in the Lagrangian of the “Standard Model”:
  - ▶ A misleading name!
    - SM is a real theory with well-developed phenomenology
    - Testable predictions
    - Describes all experimental results (except perhaps neutrino mass)

# Term “Standard Model” is an indication of our greed

- Reminds us that there are many unanswered questions
  - ▶ Does particle physics provide a solution for Dark Matter?
  - ▶ Why is gravity so much weaker than the other forces?
  - ▶ Why is there so little anti-matter in the Universe?
  - ▶ Are there extra space-time dimensions?
  - ▶ Why are there 3 generations of quarks and leptons?
- Answers to any of these questions would revolutionize our view of the world!
  - ▶ Mainstream particle physics experiments today are searching for phenomena that address all these issues

# The Standard Model Particles

Three generations of matter (fermions)

	I	II	III		
mass	2.4 MeV/c <sup>2</sup>	1.27 GeV/c <sup>2</sup>	171.2 GeV/c <sup>2</sup>	0	7 GeV/c <sup>2</sup>
charge	$\frac{2}{3}$	$\frac{2}{3}$	$\frac{2}{3}$	0	0
spin	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	1	0
name	<b>u</b> up	<b>c</b> charm	<b>t</b> top	<b>γ</b> photon	<b>H</b> Higgs boson
Quarks	4.8 MeV/c <sup>2</sup>	104 MeV/c <sup>2</sup>	4.2 GeV/c <sup>2</sup>	0	
	$-\frac{1}{3}$	$-\frac{1}{3}$	$-\frac{1}{3}$	0	
	$\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{2}$	1	
	<b>d</b> down	<b>s</b> strange	<b>b</b> bottom	<b>g</b> gluon	
Leptons	<2.2 eV/c <sup>2</sup>	<0.17 MeV/c <sup>2</sup>	<15.5 MeV/c <sup>2</sup>	91.2 GeV/c <sup>2</sup>

	<b>e</b> electron	<b>μ</b> muon	<b>τ</b> tau	<b>W<sup>±</sup></b> W boson	

Gauge bosons

- Spin  $\frac{1}{2}$  matter fields
- Spin 1 force carriers
- One fundamental scalar

# Particle physics framework based on development of quantum gauge theories

- You will study quantum gauge theories in detail in Physics 232
- Simplest such theory: Quantum Electrodynamics (QED)
  - ▶ Developed in the 1950's
  - ▶ Tested to 7 significant digit precision
  - ▶ Exhibits a number of remarkable properties that are typical of all gauge theories
    - Need for renormalization: process of subtracting unobservable infinities and retaining small, finite observable corrections
    - Identification of spin 1 field as force carrier
    - Strength of interaction depends on a universal coupling constant ( $\alpha$ )

# Introduction to QED (I)

- Describes behaviour of spin  $\frac{1}{2}$  fermions and a 4-vector potential (E&M)
- As in classical E&M,  $\mathcal{L}$  has a manifest global symmetry
  - ▶ Freedom to redefine vector potential by a gauge transformation, which does not change the equations of motion
- New in QED:
  - ▶ Postulate  $\mathcal{L}$  is invariant under *local* gauge transformations
    - This forces addition of an interaction term
    - Fermions interact with field; strength of interaction proportional to particle's charge
  - ▶ Local gauge invariance determines the nature of the fermion-field interaction, forces the photon to be massless and insures conservation of electric charge

# Introduction to QED (II)

Classically:

$$\begin{aligned}A^\mu &= (V, \vec{A}) \\ A^\mu &\rightarrow A^\mu - \partial^\mu \Lambda(x)\end{aligned}$$

Quantum Theory:

$$\psi(x) \rightarrow e^{i\theta} \psi(x)$$

Dirac Eq:

$$\mathcal{L}_{free} = \bar{\psi} (i\gamma^\mu \partial_\mu - m) \psi$$

Postulate local rather than global gauge invariance:

$$\psi(x) \rightarrow e^{i\theta(x)} \psi(x)$$

Eq. of motion not invariant unless we make the following changes

$$\begin{aligned}\partial_\mu &\rightarrow \mathcal{D}_\mu \equiv \partial_\mu + iqA_\mu(x) \\ A_\mu(x) &\rightarrow A_\mu(x) - \partial_\mu \theta(x) \\ \psi(x) &\rightarrow e^{i\theta(x)} \psi(x)\end{aligned}$$

# The QED Lagrangian

$$\begin{aligned}\mathcal{L}_{QED} &= \bar{\psi} (i\gamma^\mu \mathcal{D}_\mu - m) \psi - \frac{1}{4} F_{\mu\nu} F^{\mu\nu} \\ &= \bar{\psi} (i\gamma^\mu \partial_\mu - q\gamma^\mu A_\mu - m) \psi - \frac{1}{4} F_{\mu\nu} F^{\mu\nu} \\ &= \mathcal{L}_{Dirac} - J^\mu A_\mu - \frac{1}{4} F_{\mu\nu} F^{\mu\nu}\end{aligned}$$

where  $J^\mu = q\gamma^\mu$

- Local gauge invariance defines interaction term
  - ▶ Interaction of charged current  $J^\mu$  with photon
  - ▶ Photon must be massless: mass term  $\frac{1}{2} M_A^2 A^\mu A_\mu$  would destroy gauge invariance

# QED is a simple field theory for many reasons

- Dirac Eq plus knowledge of classical E&M makes choice of Lagrangian “obvious”
- QED vector potential is pretty simple:

$$[A_\mu, A_\nu] = 0$$

no photon self-interactions (photon has no charge)

- There is only 1 kind of photon
- There are no hidden symmetries or other wrinkles

How is the SM Different?

# Strong Interactions (I)

- Looks like QED, except gauge field more complicated
- Instead of scalar electric charges, fermion fields ( $\psi$ ) have color charge describes as a triplet of  $SU(3)_{color}$
- Gluons are a color octet of  $SU(3)$  (8 gluon states)
  - ▶  $[A_i, A_j] \neq 0$  for  $i \neq j$  “non-abelian”
  - ▶ Equivalent of  $F_{\mu\nu}$  contains an additional term that depends on this commutator
  - ▶ Gluons interact with each other as well as with quarks

- Strong coupling constant  $\alpha_s$  plays same role in theory as  $\alpha$  does in QED

# Strong Interactions (II)

- In all gauge theories, coupling strength depends on momentum transfer in interaction ( $Q$ )
- Essentially a polarization effect
  - ▶ Virtual particle-antiparticle pairs produced in vacuum
  - ▶ These shield “bare charge” of interacting particle
    - In QED, coupling increases with energy
    - In QCD, due to gluon self-coupling, coupling varies more rapidly and decreases with energy

## Behaviour of $\alpha_s$

- ▶ Low  $Q$ : non-perturbative
- ▶ High  $Q$ : perturbation theory OK
  - $\alpha_s \gg \alpha$ : slower PT convergence

# Weak Interactions (I)

- Like Strong Interactions, gauge group is non-abelian
  - ▶ But wrinkles different from the Strong Interaction case
- Attempt to unify electromagnetic and weak interactions, but in fact there are two coupling constants
  - ▶ Gauge group is  $SU(2)_L \times U(1)$

- ▶ However,  $g$  and  $g'$  are not EM and weak couplings
  - Mixing among components
  - EM basis is a combination of neutral components of  $SU(2)_L$  and  $U(1)$

# Weak Interactions: The Force Carriers

- Three vector bosons':  $W^+$ ,  $W^-$ ,  $Z^0$
- $W^\pm$  responsible for  $\beta$ -decay: changes quark and lepton flavor
- $Z$  also couples to quarks and leptons (similar to photon)
- Triple and Quartic couplings of gauge bosons to each other

# Weak Interactions: The bosons have mass

- Weak interactions not mediated by a massless field
  - ▶ Short range force
- “Weakness” comes from mass of force mediator

$$G_F \sim 10^{-5} \text{ GeV}^{-2} \Rightarrow g_W/M_W^2$$

- But how to incorporate massive boson into gauge theory?
  - ▶ Gauge invariance does not allow addition of a mass term directly into the Lagrangian
  - ▶ The solution: Electroweak Symmetry Breaking and the Higgs mechanism
    - Introduce a scalar field and a symmetry
    - Change physical basis
  - ▶  $M_W$  and  $M_Z$  predicted in terms of  $e$  and 1 additional parameter ( $\sin^2 \theta_W$ )

# The Standard Model Lagrangian

$$\begin{aligned}\mathcal{L} = & -\frac{1}{4}F_{\mu\nu}^a F^{a\mu\nu} + i\bar{\psi}D\psi \\ & + \psi_i\lambda_{ij}\psi_j h + \text{h.c.} \\ & + |D_\mu h|^2 - V(h) \\ & + \frac{1}{M}L_i\lambda_{ij}^\nu L_j h^2 \text{ or } L_i\lambda_{ij}^\nu N_j\end{aligned}$$

gauge sector

flavour sector

Higgs sector

$\nu$  mass sector

- $\mathcal{L} = \mathcal{L}_{QCD} + \mathcal{L}_{EW}$
- Gauge group:  $SU(3) \times SU(2)_L \times U(1)$

# Beyond the SM

- In SM, all forces described by local gauge theories
  - ▶ What about gravity?
    - Spin-2 graviton not easily added
  - ▶ String theory a natural extension
    - Gauge theory as a low energy manifestation
- All forces defined in terms of symmetry properties
  - ▶ Can embed gauge group in larger group that “unifies” them
    - One coupling constant rather than 3
    - Grand Unified Theory (GUT)
  - ▶ Expected scale for unification  $\sim 10^{15}$  GeV
    - Extra space-time dimensions can bring scale down
  - ▶ Can also add additional symmetries
    - Eg Supersymmetry (SUSY)

# The Role of Experiment

- In QED:
  - ▶ Observation: EM has global gauge invariance
  - ▶ Theory: Postulate of local invariance leads to predictions
  - ▶ Experimental measurements validated approach
    - $g - 2$ , Lamb shift
- In SM:
  - ▶ Matter content determined from experiment
  - ▶ Underlying symmetries determined from experiment
  - ▶ These define Lagrangian
  - ▶ Theoretical predictions possible once Lagrangian is known
  - ▶ Experimental measurements validate or refute the theory
- BSM:
  - ▶ Theorists postulate new forces and interactions
  - ▶ Experimentalists look: find or rule out

# Just because a theory is beautiful, doesn't mean it is correct!

- Example: SU(5) GUT
  - ▶ Developed by Georgi and Glashow in 1974
  - ▶ Simplest possible GUT
    - $SU(5) \supset SU(3) \times SU(2) \times U(1)$
    - One fundamental coupling constant
    - Quarks and leptons in same multiplets
  - ▶ Beautiful theory that should have been right! But:
    - Predicts proton decay with lifetime  $10^{30 \pm 2}$  years
    - Searches for proton decay (large water Cherenkov detectors) set lifetime limits outside predictions of minimal SU(5)
  - ▶ More complicated GUT theories still allowed

# Particle physics experiment: The 3 frontiers

- Energy Frontier
  - ▶ Use high energy colliders to discover new particles and new interactions and directly probe the fundamental forces
- Intensity Frontier
  - ▶ Use intense particle beams or large mass detectors to uncover the properties of neutrinos and to observe rare processes that involve other elementary particles
- Cosmic Frontier
  - ▶ Use underground experiments and telescopes to study Dark Matter and Dark Energy. Use high energy particles from space to search for new phenomena

# High Energy: Probing small distance structure

- Spatial resolution limited by wavelength of probe
  - ▶ Microscope: visible light  $\lambda \sim 1\mu\text{m} \rightarrow$  cell structure
  - ▶ Higher energy particles:  $\lambda = 2\pi\hbar/p$ 
    - $\hbar c \sim 200 \text{ MeV fm}$
  - ▶ X rays:  $\lambda \sim 0.01\text{-}10 \text{ nm} \rightarrow$  atomic crystal structure
- Charged particles:
  - ▶ Rutherford experiment:  $p \sim 10 \text{ keV}$   $\lambda \sim 10^{-10} \text{ m}$
  - ▶ Discovery of quarks:  $p \sim 10 \text{ GeV}$ ,  $\lambda \sim 10^{-16} \text{ m}$
  - ▶ LHC:  $p \sim 1\text{-}10 \text{ TeV}$ ,  $\lambda \sim 10^{-18} - 10^{-19} \text{ m}$ 
    - Can search for substructure (eg for quarks)

# High Energy: Production of massive particles

- Energy mass equivalence:  $E = mc^2$
- Mechanism for creating new massive particles:  
particle-antiparticle annihilation

- $e^+e^-$  collider

- ▶ Electrons have no internal structure
  - All energy used to make new particles
- ▶ But electrons have small mass: radiate when accelerated

- Hadron collider

- ▶ Protons made of  $q$  and  $g$ 
  - Hard collision uses only fraction of energy
- ▶ Protons heavy: less radiation when accelerated

# High Intensity: Direct probes of large mass

- Virtual corrections have measureable effects
  - ▶ Ability to calculate size of these effects well established
    - $g = 2$ , precision measurements of  $Z$ -boson properties
- Size of correction depends on mass of exchanged particle
- If exchanged particle allows interactions forbidden by other processes, search for it through its virtual effects

Lepton flavor violation:  $\mu + N \rightarrow e + N^*$

Proton decay in a GUT

# Large Volume: Probing rare phenomena

- If process rare, need many opportunities to see it
- Examples:
  - ▶ Neutrino interactions
  - ▶ Dark Matter (WIMPs)
- Detector is also the target
- Beams from accelerators or incident particles from outer space

3D schematic of NOvA particle detector

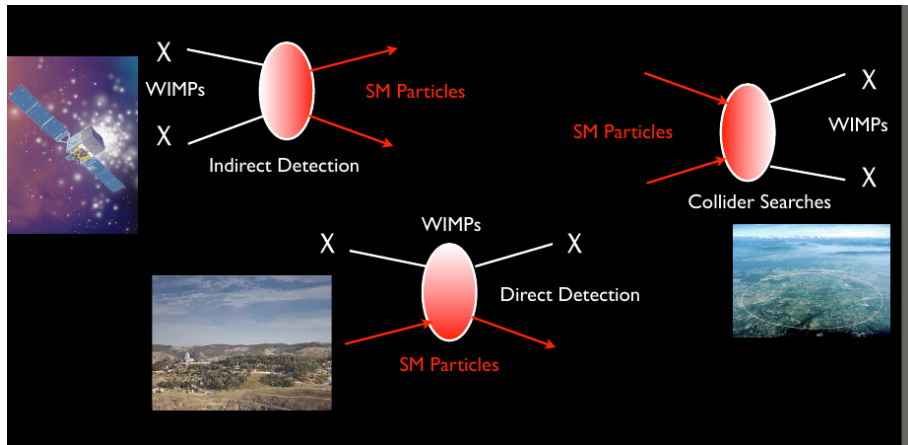

# The Cosmic Frontier

- Most of the universe is not made of the particles we study in the lab
- Understanding Dark Matter and Dark Energy central to particle physics, although techniques used are quite different
- Significant synergy between particle physics and cosmology

# Dark Matter: Three Complementary Approaches

Tim Tait: DarkMatter LHC 2013

# Our program for the semester

- Experimental tools (2 weeks)
  - ▶ Detectors and accelerators
  - ▶ Statistics and probability
  - ▶ Fitting and other mathematical methods
- Particle physics basics (1.5 weeks)
  - ▶ Symmetries and conservation laws
  - ▶ Cross sections and Feynman diagrams
- Strong interactions (3 weeks)
  - ▶ Structure of the proton
  - ▶ The QCD Lagrangian
  - ▶ Hadronization
  - ▶ Quarkonium
- Weak Interactions (3.5 weeks)
  - ▶ Weak decays
  - ▶ C, P and CP
  - ▶ CKM Matrix
  - ▶  $K\bar{K}$  and  $B\bar{B}$  Mixing
  - ▶ Neutral currents
- Hadron colliders (1.5 weeks)
  - ▶ Jet production
  - ▶ Electroweak bosons
  - ▶ The top quark
  - ▶ EWSB and the Higgs
- Current topics (2 weeks)
  - ▶ SUSY and GUTS
  - ▶ Dark Matter
  - ▶ Neutrinos
